Neural Network Basics

function (sigmoid, tanh, ReLU, ...).

LATEST SUBMISSION GRADE

1. What does a neuron compute?

100%

A neuron computes a function g that scales the input x linearly (Wx + b)
 A neuron computes the mean of all features before applying the output to an activation function
 A neuron computes a linear function (z = Wx + b) followed by an activation function
 A neuron computes an activation function followed by a linear function (z = Wx + b)

Correct, we generally say that the output of a neuron is a = g(Wx + b) where g is the activation

1 / 1 point

1 / 1 point

2. Which of these is the "Logistic Loss"?

What will be the shape of "c"?

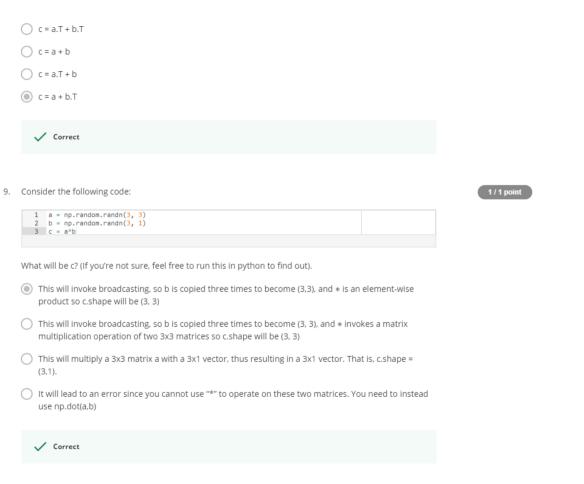

- c.shape = (2, 3)
- c.shape = (3, 2)
- c.shape = (2, 1)
- The computation cannot happen because the sizes don't match. It's going to be "Error"!

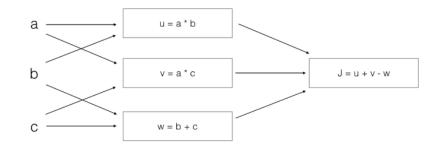

Correct
Yes! This is broadcasting. b (column vector) is copied 3 times so that it can be summed to each column of a.

5.	Consider the two following random arrays "a" and "b":	1 / 1 point
	1 a = np.random.randn(4, 3) # a.shape = (4, 3) 2 b = np.random.randn(3, 2) # b.shape = (3, 2) 3 c = a*b	
	What will be the shape of "c"?	
	c.shape = (4,2)	
	c.shape = (3, 3)	
	The computation cannot happen because the sizes don't match. It's going to be "Error"!	
	c.shape = (4, 3)	
	Correct Indeed! In numpy the "*" operator indicates element-wise multiplication. It is different from "np.dot()". If you would try "c = np.dot(a,b)" you would get c.shape = (4, 2).	
6.	Suppose you have n_x input features per example. Recall that $X=[x^{(1)}x^{(2)}x^{(m)}].$ What is the dimension of X?	1/1 point
	\bigcirc (n_x,m)	
	\bigcirc $(1,m)$	
	$\bigcirc \ (m,n_x)$	
	\bigcirc $(m,1)$	

```
7. Recall that "np.dot(a,b)" performs a matrix multiplication on a and b, whereas "a*b" performs an element-
                                                                                                                1 / 1 point
   wise multiplication.
   Consider the two following random arrays "a" and "b":
      1 a = np.random.randn(12288, 150) # a.shape = (12288, 150)
      2 b = np.random.randn(150, 45) # b.shape = (150, 45)
     3 c = np.dot(a.b)
   What is the shape of c?
   c.shape = (12288, 150)
   c.shape = (150,150)
   The computation cannot happen because the sizes don't match. It's going to be "Error"!
   c.shape = (12288, 45)
       ✓ Correct
           Correct, remember that a np.dot(a, b) has shape (number of rows of a, number of columns of b).
           The sizes match because:
           "number of columns of a = 150 = number of rows of b"
8. Consider the following code snippet:
                                                                                                               1 / 1 point
      1 # a.shape = (3,4)
       2 # b.shape = (4,1)
      4 ▼ for i in range(3):
      5 v for j in range(4):
```

How do you vectorize this?

What is the output J?

$$\int J = (c - 1)*(b + a)$$

$$\int J = a*b + b*c + a*c$$
