1. Which notation would you use to denote the 3rd layer's activations when the input is the 7th example from the 8th minibatch?

1 / 1 point

- a<sup>[3]{7}(8)</sup>
- $a^{[3]\{8\}(7)}$
- $\bigcirc \ a^{[8]\{7\}(3)}$
- $\bigcirc a^{[8]\{3\}(7)}$

✓ Correct

2. Which of these statements about mini-batch gradient descent do you agree with?

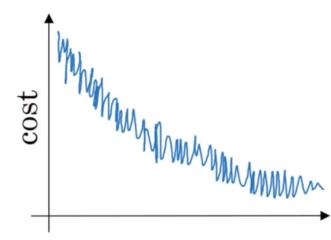

0 / 1 point

- Training one epoch (one pass through the training set) using mini-batch gradient descent is faster than training one epoch using batch gradient descent.
- You should implement mini-batch gradient descent without an explicit for-loop over different mini-batches, so that the algorithm processes all mini-batches at the same time (vectorization).

	iteration of mini-batch gradient descent (computing on a single mini-batch) is faster than one iteration of batch gradient descent.	
	Incorrect	
3.	Why is the best mini-batch size usually not 1 and not m, but instead something in-between?	1 / 1 point
	If the mini-batch size is 1, you end up having to process the entire training set before making any progress.	
	If the mini-batch size is 1, you lose the benefits of vectorization across examples in the mini-batch.	
	✓ Correct	
	If the mini-batch size is m, you end up with batch gradient descent, which has to process the whole training set before making progress.	
	✓ Correct	
	If the mini-batch size is m, you end up with stochastic gradient descent, which is usually slower than mini-batch gradient descent.	

1 / 1 point

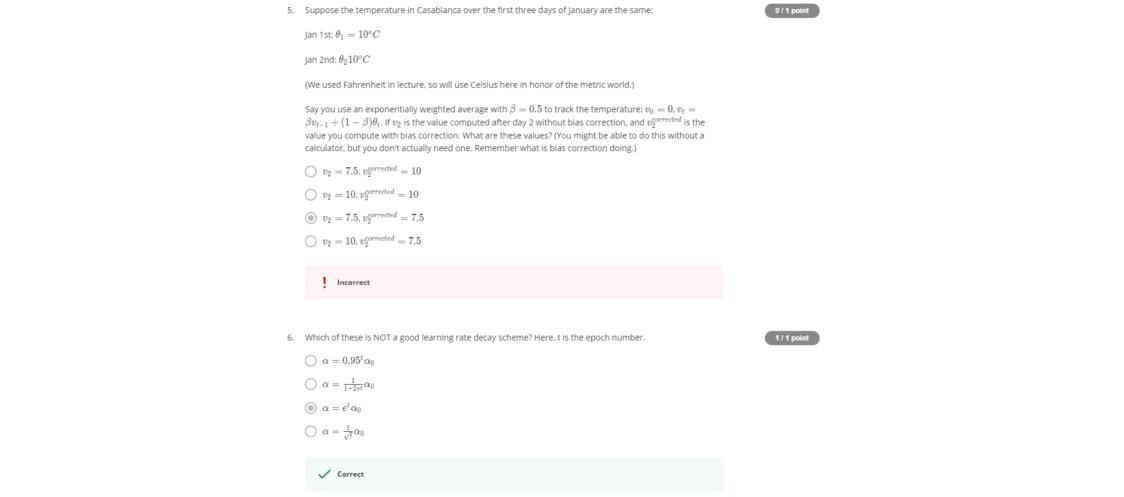

4. Suppose your learning algorithm's cost J, plotted as a function of the number of iterations, looks like this:

Which of the following do you agree with?

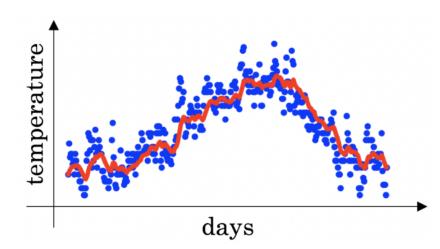

- If you're using mini-batch gradient descent, this looks acceptable. But if you're using batch gradient descent, something is wrong.
- Whether you're using batch gradient descent or mini-batch gradient descent, something is wrong.
- Whether you're using batch gradient descent or mini-batch gradient descent, this looks acceptable.
- If you're using mini-batch gradient descent, something is wrong. But if you're using batch gradient descent, this looks acceptable.

7. You use an exponentially weighted average on the London temperature dataset. You use the following to track the temperature:  $v_t = \beta v_{t-1} + (1-\beta)\theta_t$  . The red line below was computed using  $\beta = 0.9$  . What would happen to your red curve as you vary eta? (Check the two that apply)

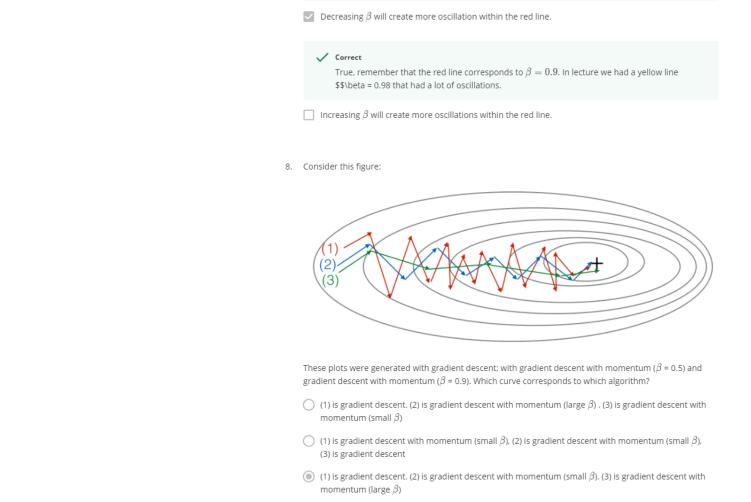

1 / 1 point

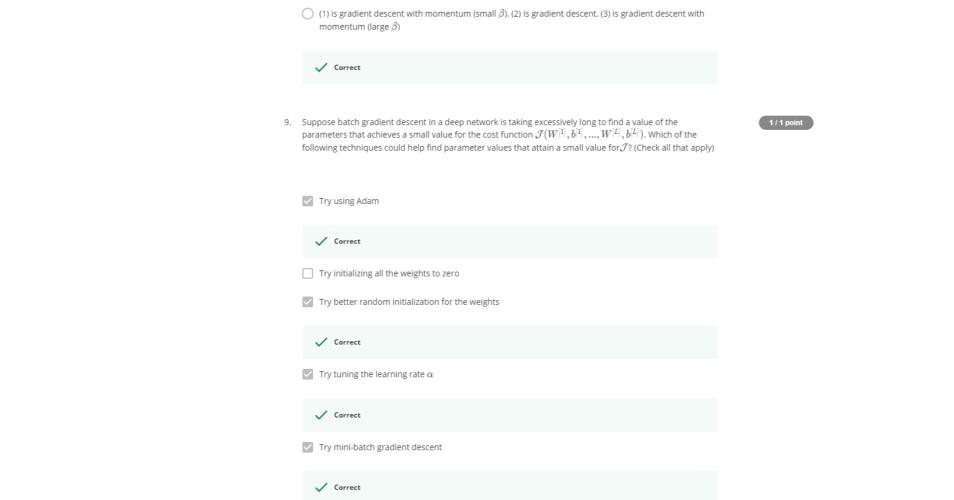

- ightharpoonup Increasing eta will shift the red line slightly to the right.

✓ Correct

True, remember that the red line corresponds to eta=0.9. In lecture we had a green line \$\$\beta = 0.98) that is slightly shifted to the right.

$$\bigcirc$$
 The learning rate hyperparameter  $lpha$  in Adam usually needs to be tuned.

The learning rate hyperparameter 
$$lpha$$
 in Adam usually needs to be tuned.

$$\bigcirc$$
 We usually use "default" values for the hyperparameters  $\beta_1,\beta_2$  and  $\varepsilon$  in Adam ( $\beta_1=0.9,\beta_2=0.999,\varepsilon=10^{-8})$
